1. Introduction

The ICON (ICOSahedral Nonhydrostatic) modelling framework is a joint development by the German Weather Service (DWD) and the Max-Planck-Institute for Meteorology (MPI-M). ICON is a global model with the possibility for regional refinement over selected areas with two-way interactions. It is used by the DWD for numerical weather predictions and will be used by MPI-M for climate projections.

We extended ICON by modules for gas-phase chemistry and aerosol dynamics (ART, Aerosols and Reactive Tracer gases). Up to now, ICON-ART accounts for multiple aerosols¹. Additionally, several gaseous tracers have been introduced. For the dynamics (transport and diffusion) of aerosol and gaseous tracers, the original ICON tracer framework is used. For the model physics, numerical time integration follows a process splitting approach separating physical processes. Each process is called independently via an interface module. Currently, the processes of emission, dry and wet deposition, sedimentation, and first order chemical reactions are included.

We will present both, long term and short term simulations of different chemical and artificial tracers to account for the potential of ICON for simulations on climatological timescales as well as the prediction of single events from the troposphere up to the stratosphere.

2. Key Questions

What is the dynamical behaviour of ICON on different time scales?
What is the ability of ICON-ART to simulate vertical transport in the troposphere as well as of large-scale stratospheric dynamics?

3. Simulations

4. Long-term Simulations

A suitable measure for large scale transport mechanism on climatological timescales is the so called age of air. This artificial tracer is emitted only at the bottom layer, has no source or sink terms in the atmosphere and its emission increases linear with time. At start-up it’s initialized with an assumed age of air which ranges from 0 at bottom to 7 years at top layer (Fig. 1).

A second tracer added to ICON-ART is methane. Methane is one of the major radiative greenhouse gases and the main source for water vapour in the stratosphere. Despite its importance it’s still too simple represented in most numerical models. We present two different methane parametrizations. One following the approach of ECMWF (Fig. 2) the other taken from Brasseur and Solomon (Fig. 3). Both base on a lifetime approach which varies with height.

Another source for water vapour in the stratosphere is the transport through the tropopause. Due to seasonal cycles in tropopause temperatures and therefore dry-freezing of water vapour, the amount which is transported upward differs². This effect, known as the tropical transport, is used to investigate the upward propagating velocity of ICON-ART.

5. Short-term Simulations

To test the ability to forecast large scale stratospheric dynamics, ICON-ART was used to simulate the unique Antarctic stratospheric vortex split event in September 2002. Therefore a linearized ozone chemistry was introduced³. The parameterization depends on a set of tabulated coefficients for net production, concentration, column of ozone and temperature. Additionally a simple approach for polar chemistry has been used which depends on solar zenith angle and temperature. Ozone VMR was initialized with GEMS climatology.

In future work the effect of feedback mechanism of ozone, changes in greenhouse gases and SST/SIC will be examined. Additionally a second artificial tracer will be added to investigate the convective stratosphere troposphere exchange during the TORERO campaign.

6. Summary & Outlook

The results of the long-term simulations indicate that ICON performs well on climatological timescales. Key features of the atmosphere like large scale dynamics and convective transport are in agreement with other model studies, though the upward transport is too fast, leading to too small age of air and a too fast tape recorder in the stratosphere.

The results of the short-term simulations show that ICON is able to predict the stratospheric vortex split and that the simulated ozone agrees well with TOMS data.

In future work the effect of feedback mechanism of ozone, changes in greenhouse gases and SST/SIC will be examined. Additionally a second artificial tracer will be added to investigate the convective stratosphere troposphere exchange during the TORERO campaign.
